

From Tactile to Virtual: Using a Smartwatch to Improve Spatial Map Exploration for Visually Impaired Users

Sandra Bardot, Marcos Serrano, Christophe Jouffrais

IRIT (Computer Science Research Institute) - University of Toulouse & CNRS, FRANCE

Context

Maps for visually impaired people:

Education

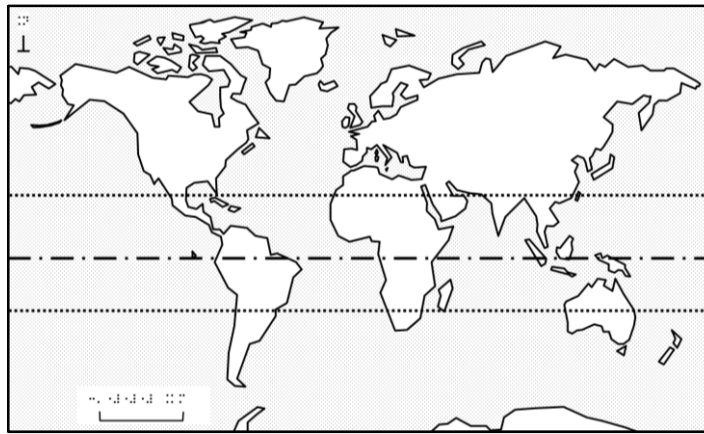

Mobility

Autonomy

Raised-line map: common tool

Context

Raised-line maps:

Content simplified

Content cannot be modified

Need interactive maps

Related work

Interactive maps

4

[Miele et al., 2006]

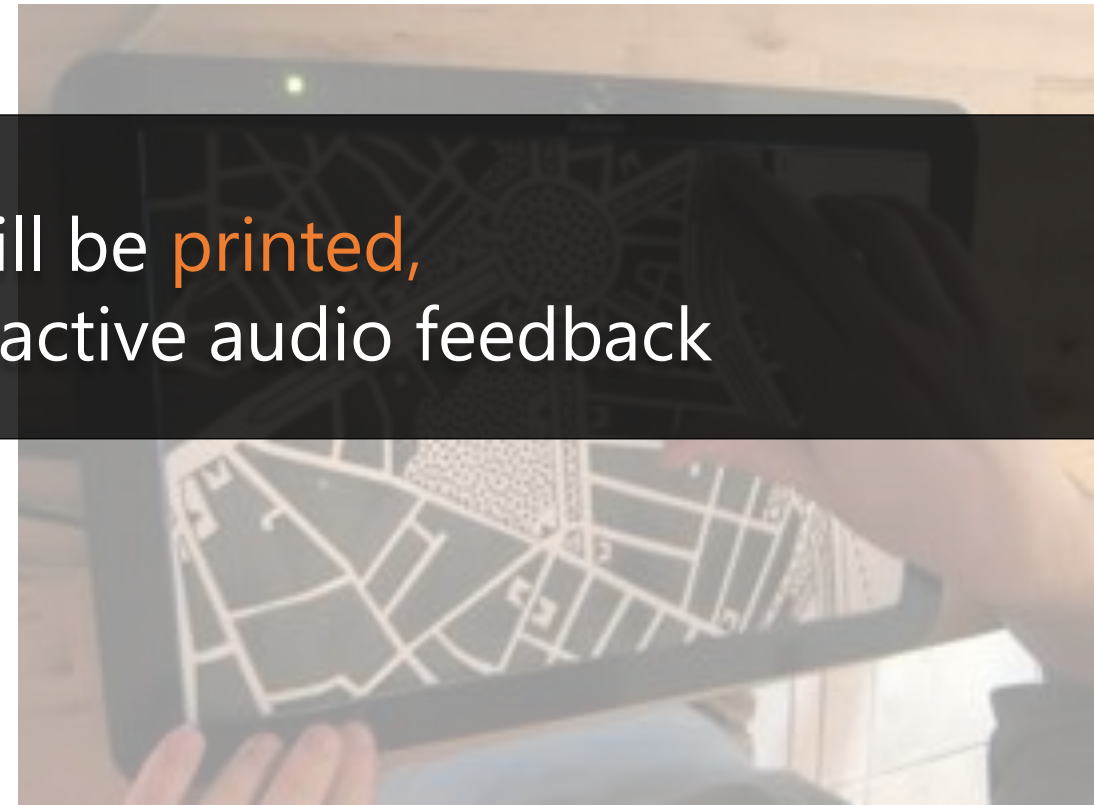

[Brock et al., 2014]

Related work

Interactive maps

Raised line map must still be **printed**, thus **limiting the benefits** of interactive audio feedback

Related work

6 *[McGookin et al., 2010]*

Tangible maps

[Ducasse et al., 2016]

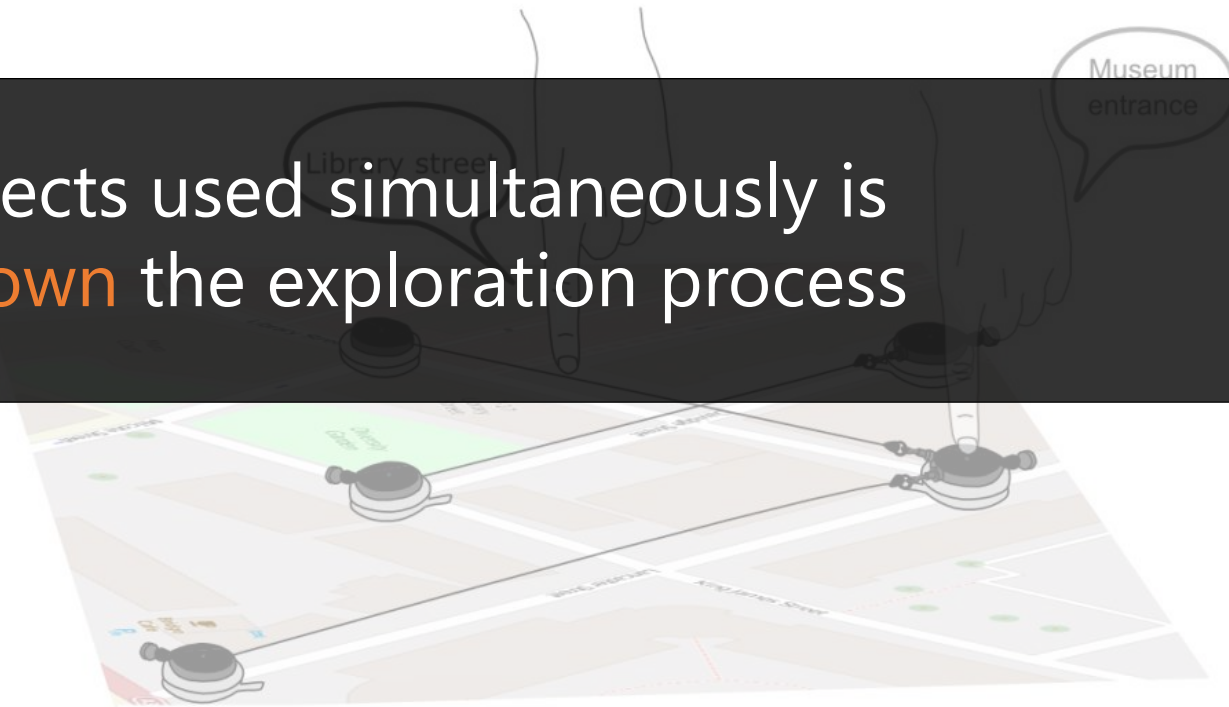

Related work

Tangible maps

The number of physical objects used simultaneously is **limited** and tends to **slow down** the exploration process

7 *[McGookin et al., 2010]*

[Ducasse et al., 2016]

Related work

[Zhao et al., 2008]

Virtual maps

[Goncu et al., 2015]

Related work

[Zhao et al., 2008]

Virtual maps

[Goncu et al., 2015]

Related work

Keyboard exploration is strictly discrete, required more cognitive effort

[Zhao et al., 2008]

Virtual maps

[Goncu et al., 2015]

Related work

[Zhao et al., 2008]

Virtual maps

Provide a **limited surface** for exploration and require recurrent **panning and zooming** operations

[Goncu et al., 2015]

Research Goals

- 1) Improve the spatial direct exploration
- 2) Provide the user with large surfaces and collocated feedback
- 3) Provide the user with map access in any situation (home, school, work, etc.)

Proposed technique

Hand tracking

Frequent and cheap

Smartwatch

Personal device

Provide audio and vibrotactile feedback

Source: <http://venturebeat.com/2016/08/28/leap-motions-interaction-engine-puts-the-hand-into-hand-tracking/>

Proposed technique

Smartwatch use as input and output

Design 3 versions of the technique:

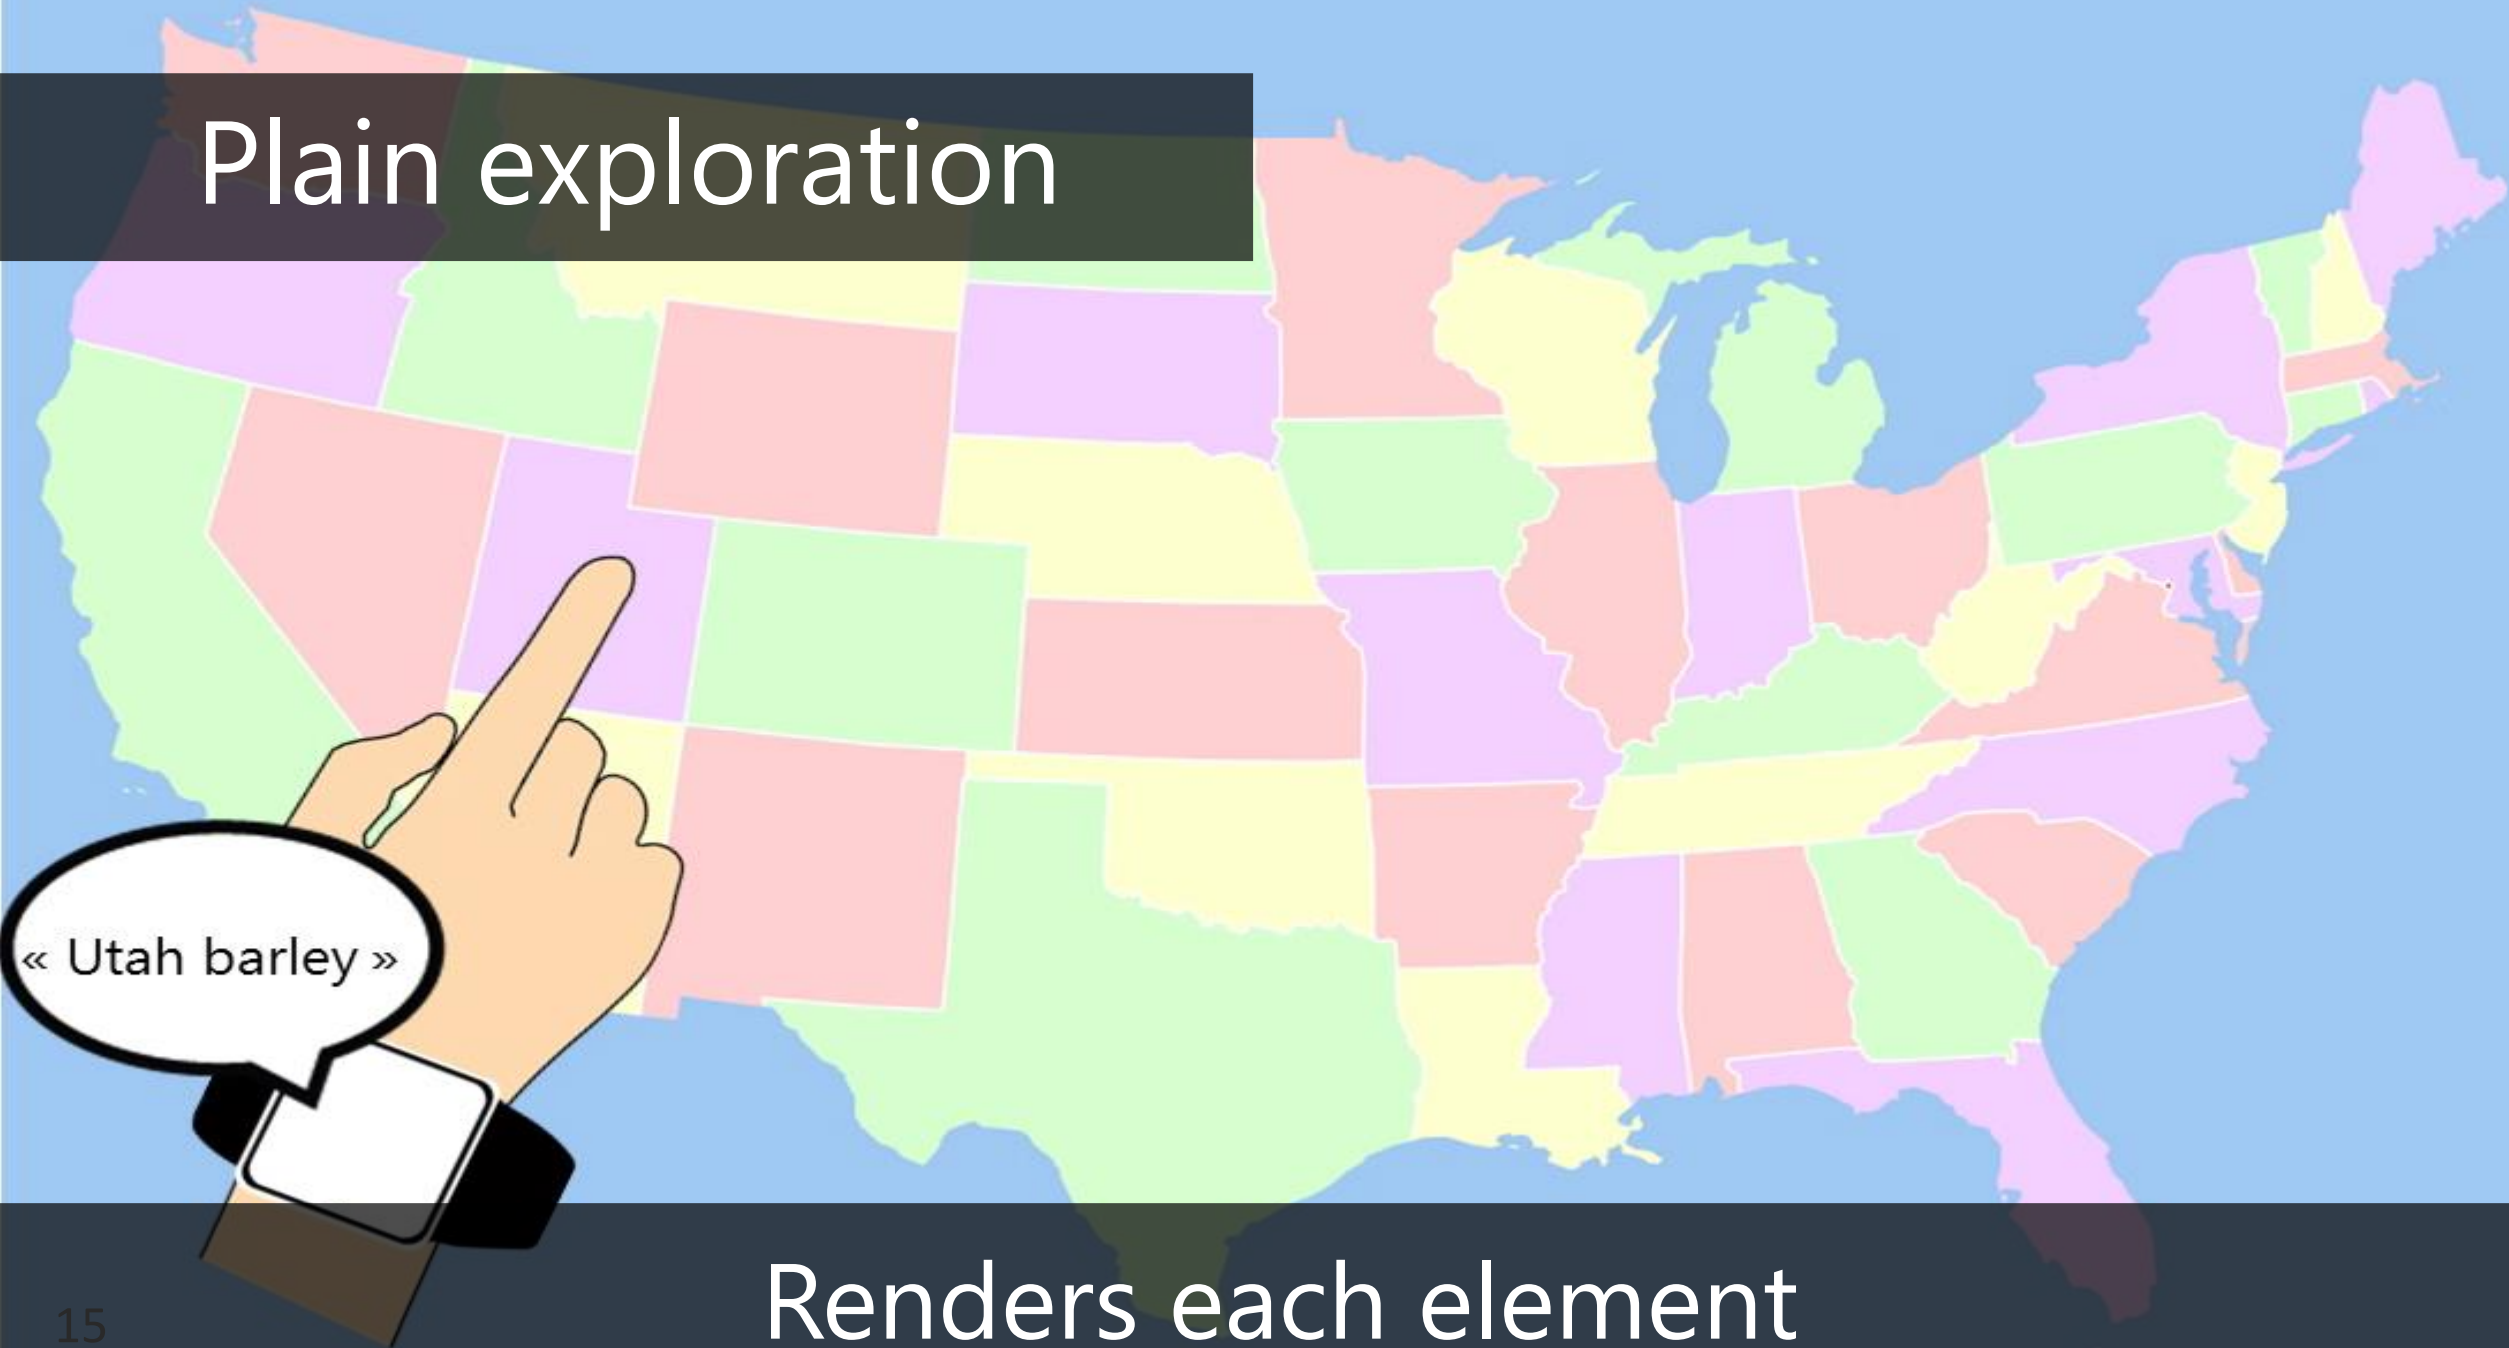

Plain

Filter

Grid + Filter

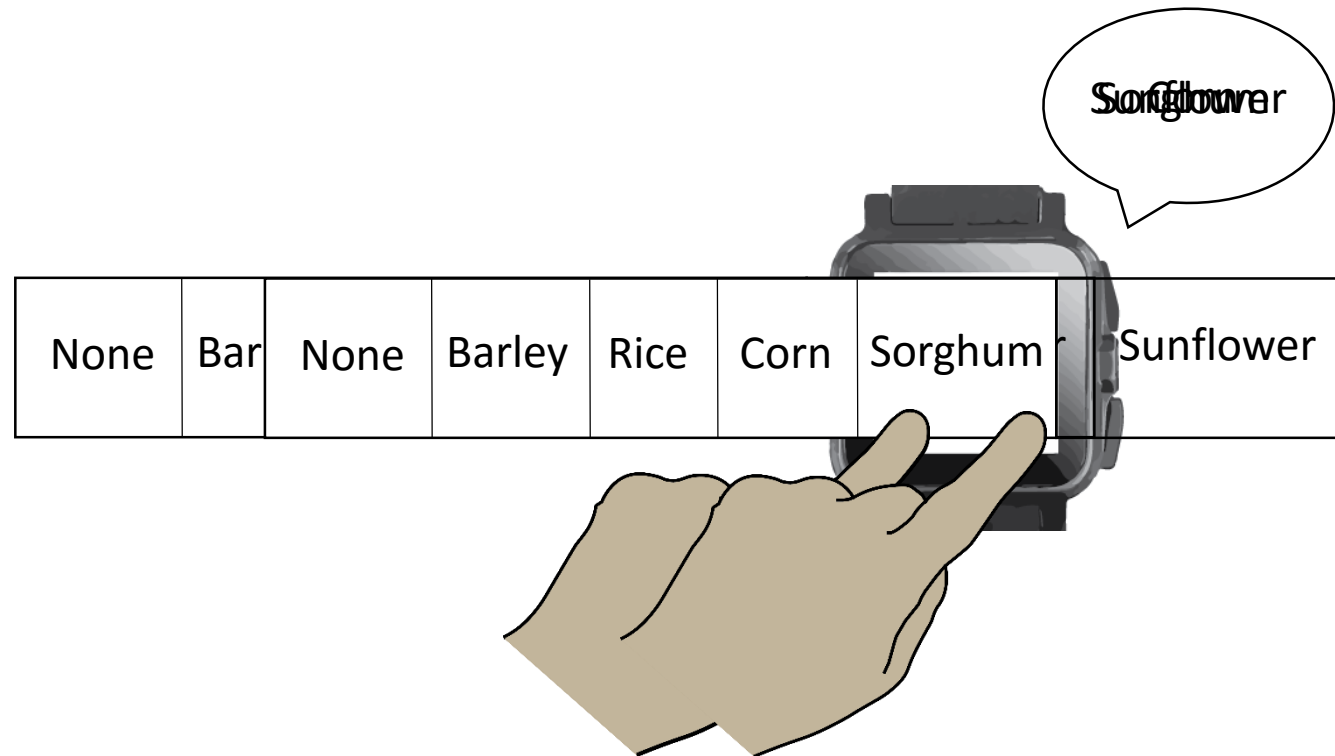

Plain exploration

Renders each element

Filter exploration

Swipe gesture to select a data

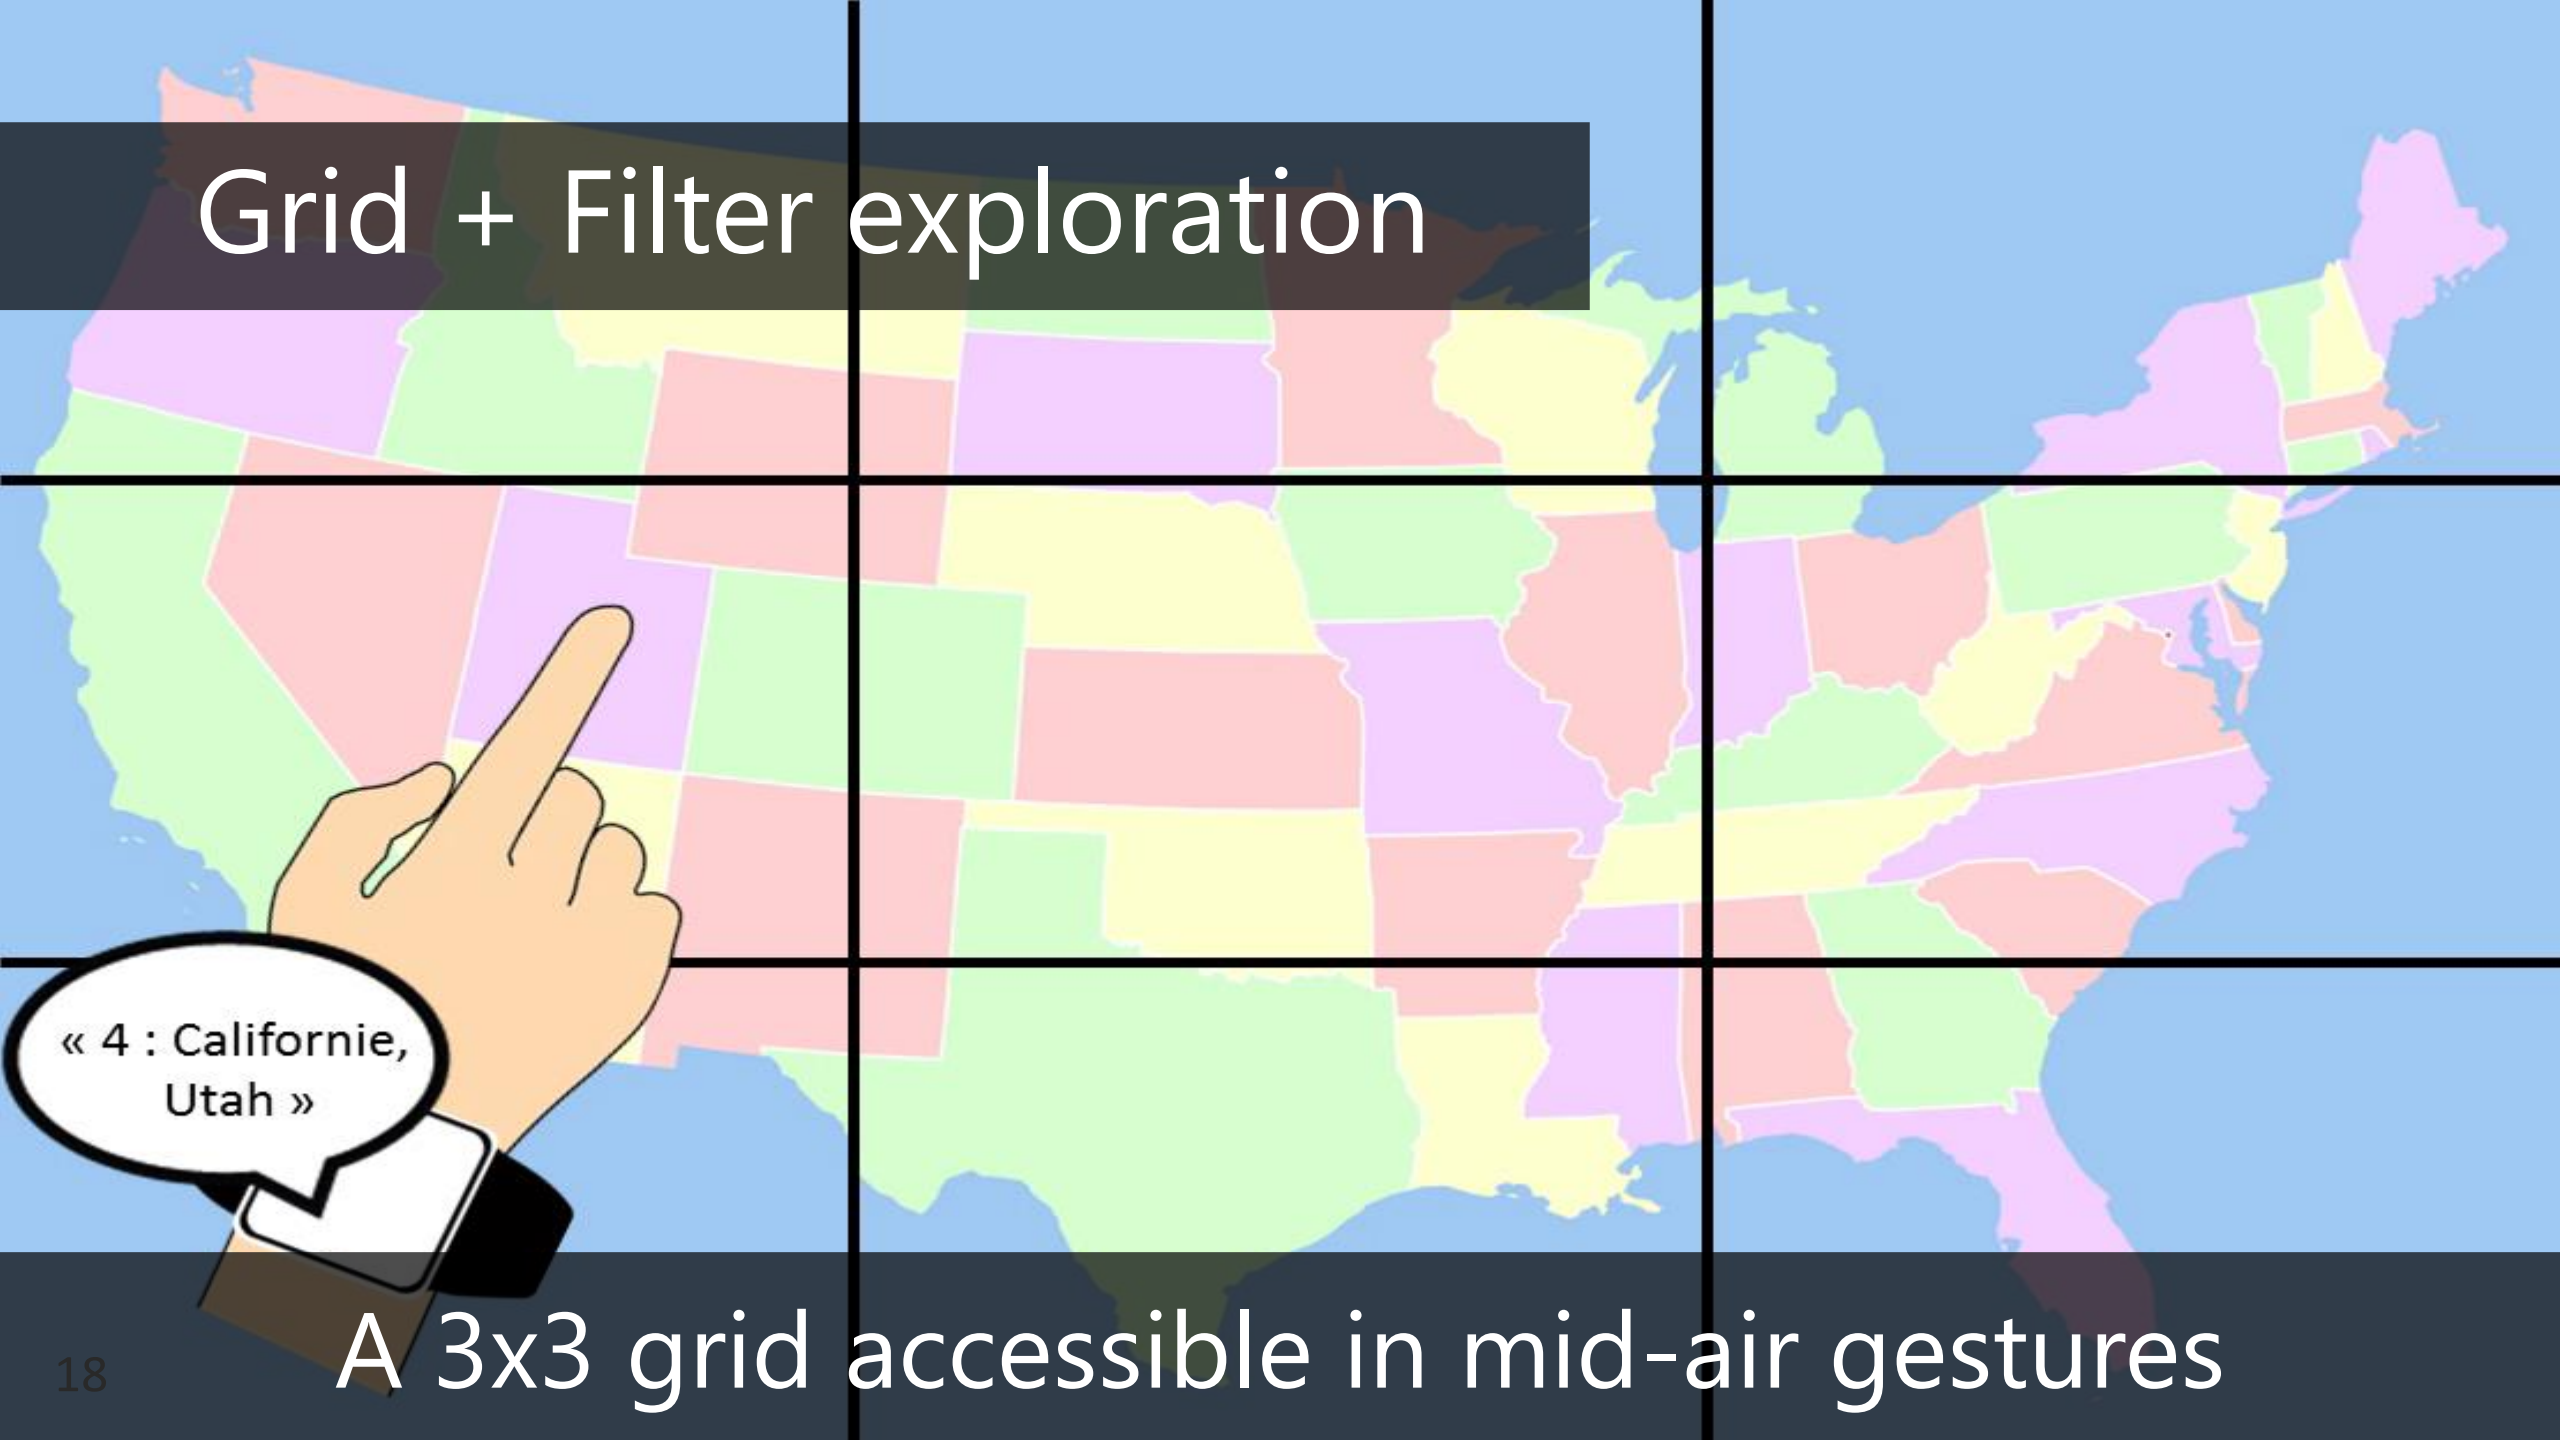

Filter exploration

Renders a sub-range of values

Grid + Filter exploration

Study

Goal: Compare the usability of our 3 techniques vs raised-line printed

Task: Find 4 specific regions

12 visually impaired people

4 techniques

Study

3 types of maps: 30, 45 and 60 regions

Randomly generate regions

Measures:

- Time
- Accuracy
- User preference

Apparatus

8 infrared cameras

Markers on index finger

Android Smartwatch SimValley

Google TTS

User test to define parameters of the smartwatch

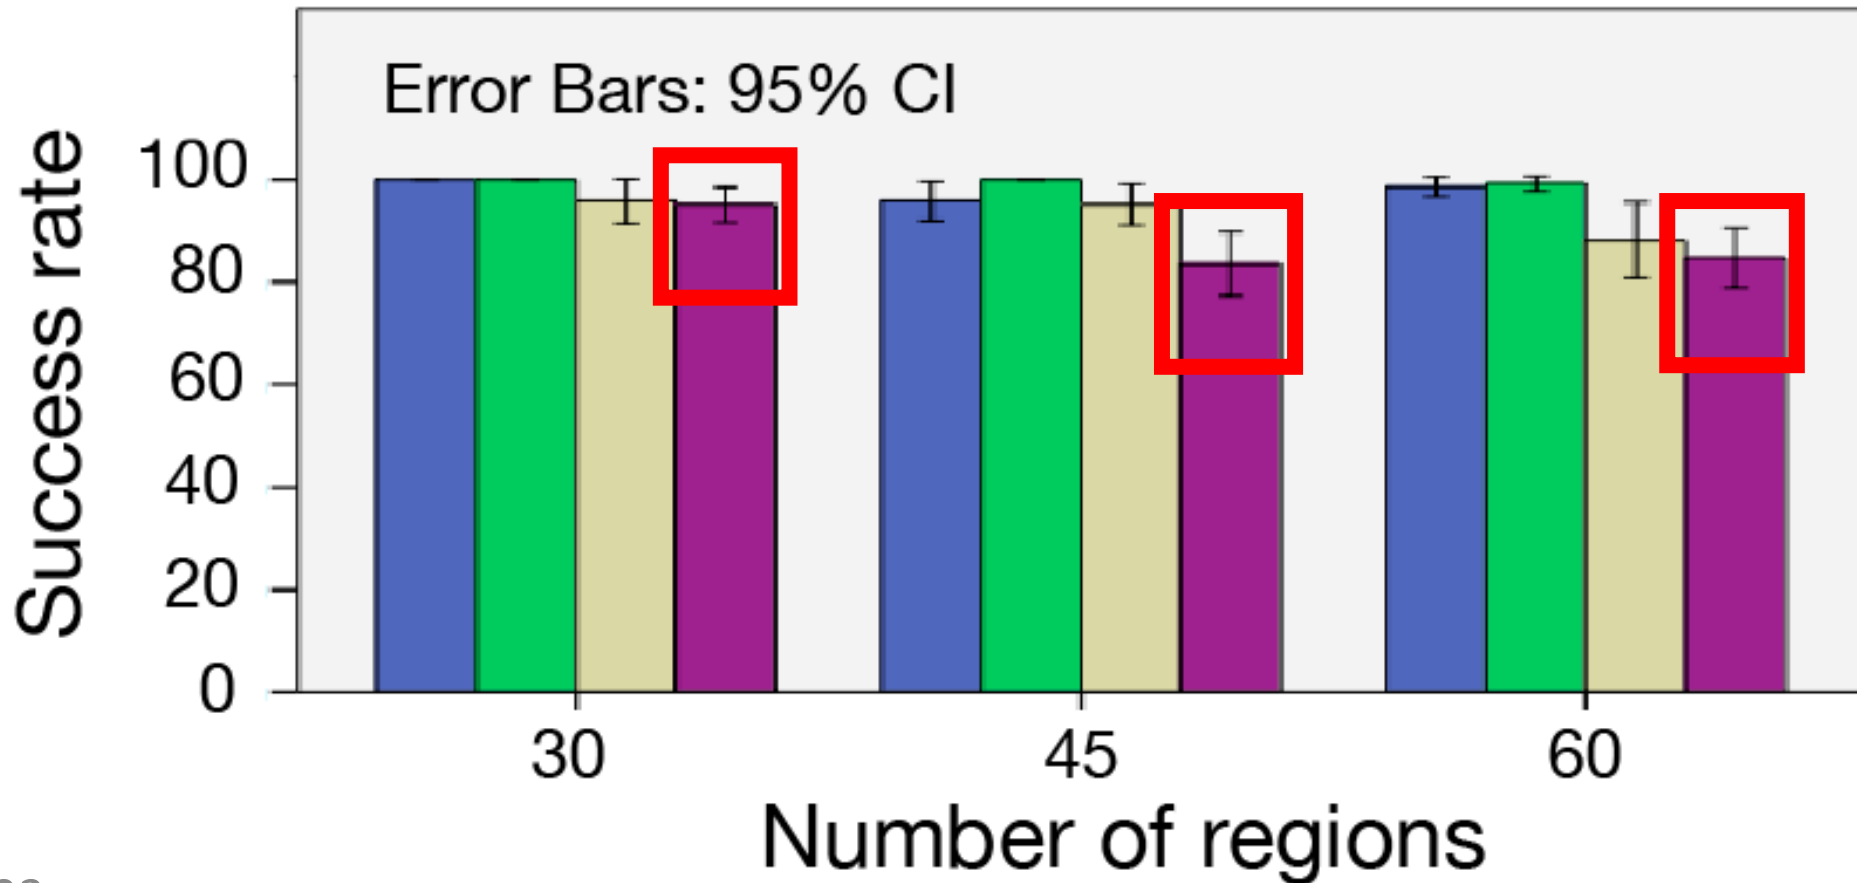

Time performance

Accuracy

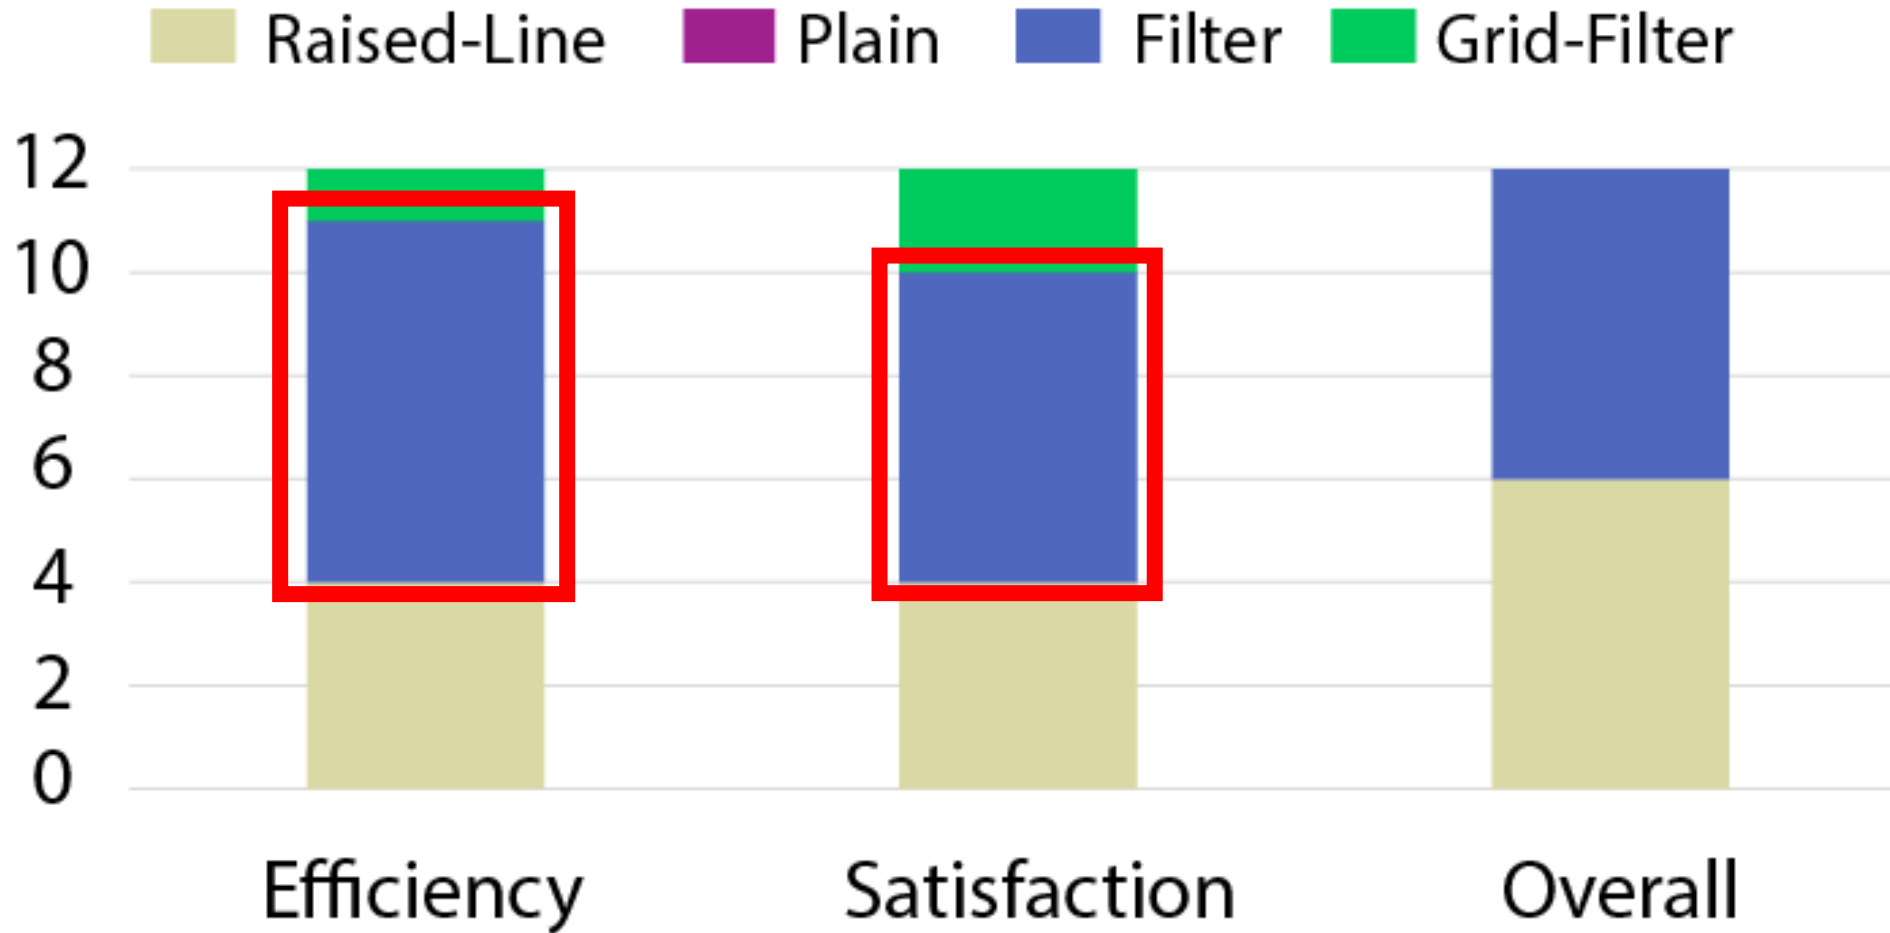

■ Raised-Line ■ Plain ■ Filter ■ Grid-Filter

User preference

Number of participants

Qualitative study – Real case

2 techniques: Filter and Grid-Filter

Exploring with two types of data: population and unemployment

4 visually impaired people

Task: Find data correlation trends in spatial data visualization

Summary

Data correlation

Get the two values at the same time, on the same map was convenient (P1)

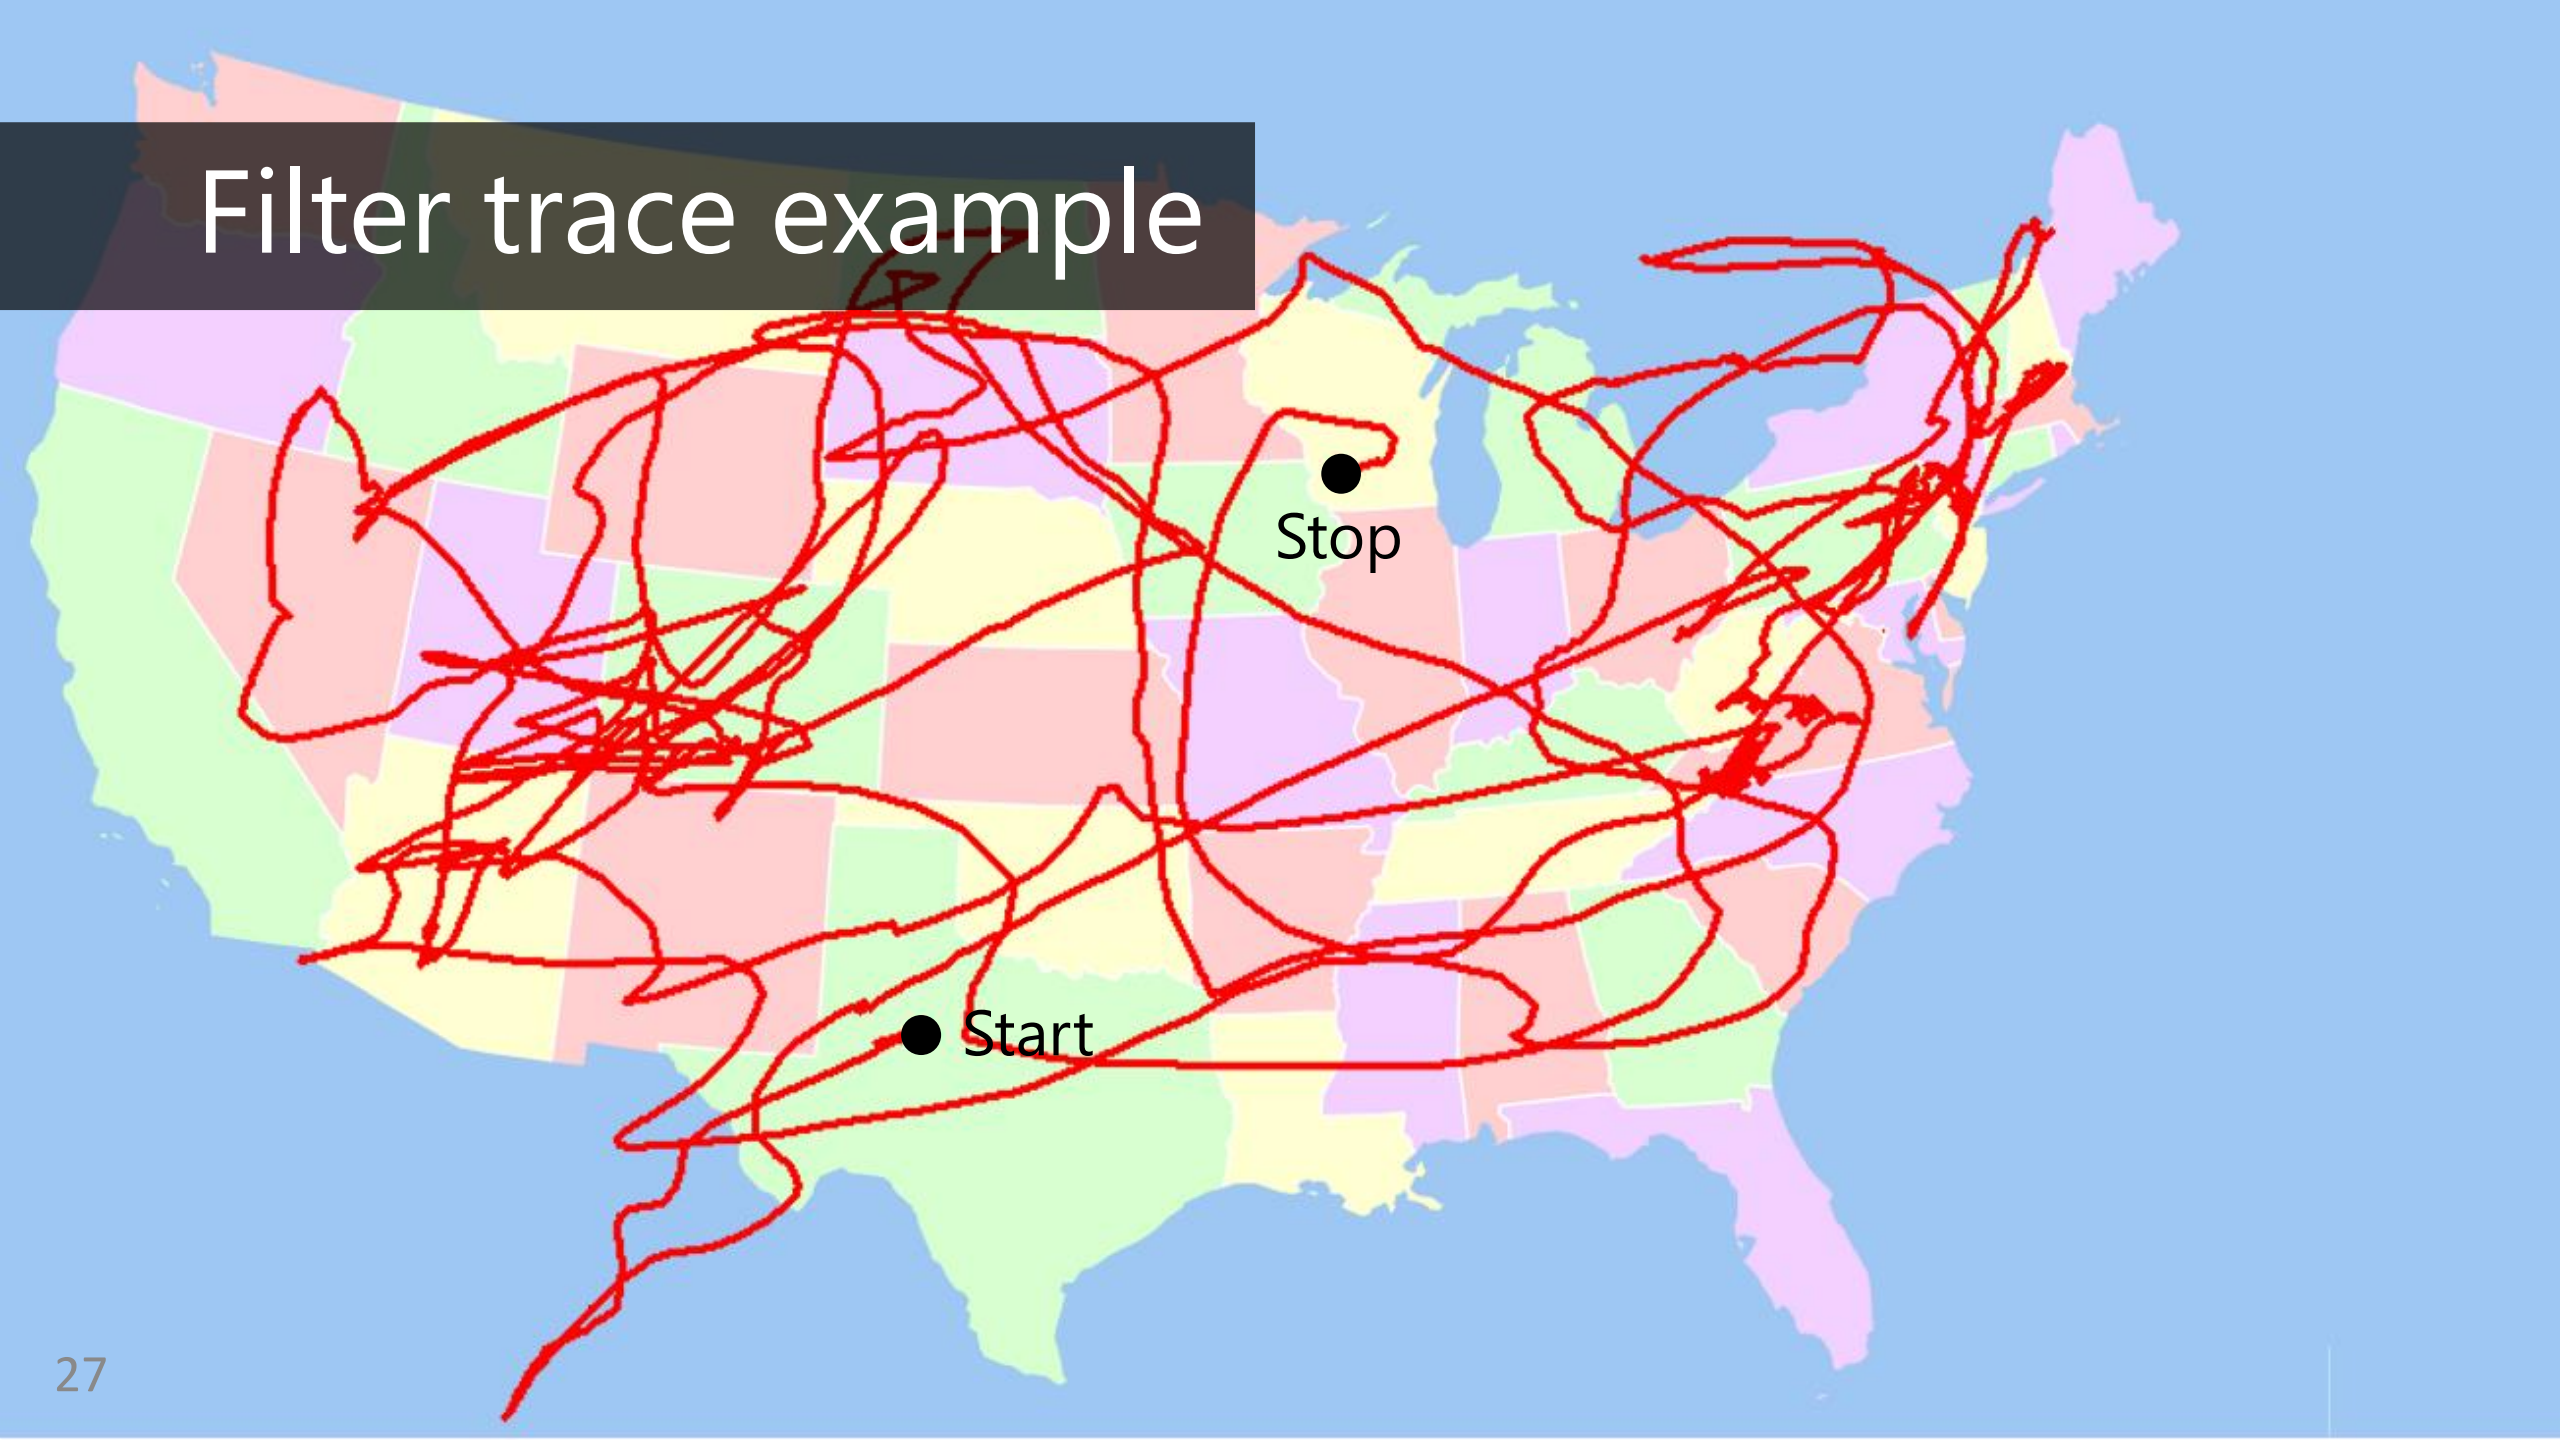

Swipe gesture

Perform horizontal and vertical swipes to filter data systematically (P1, P3, P4)

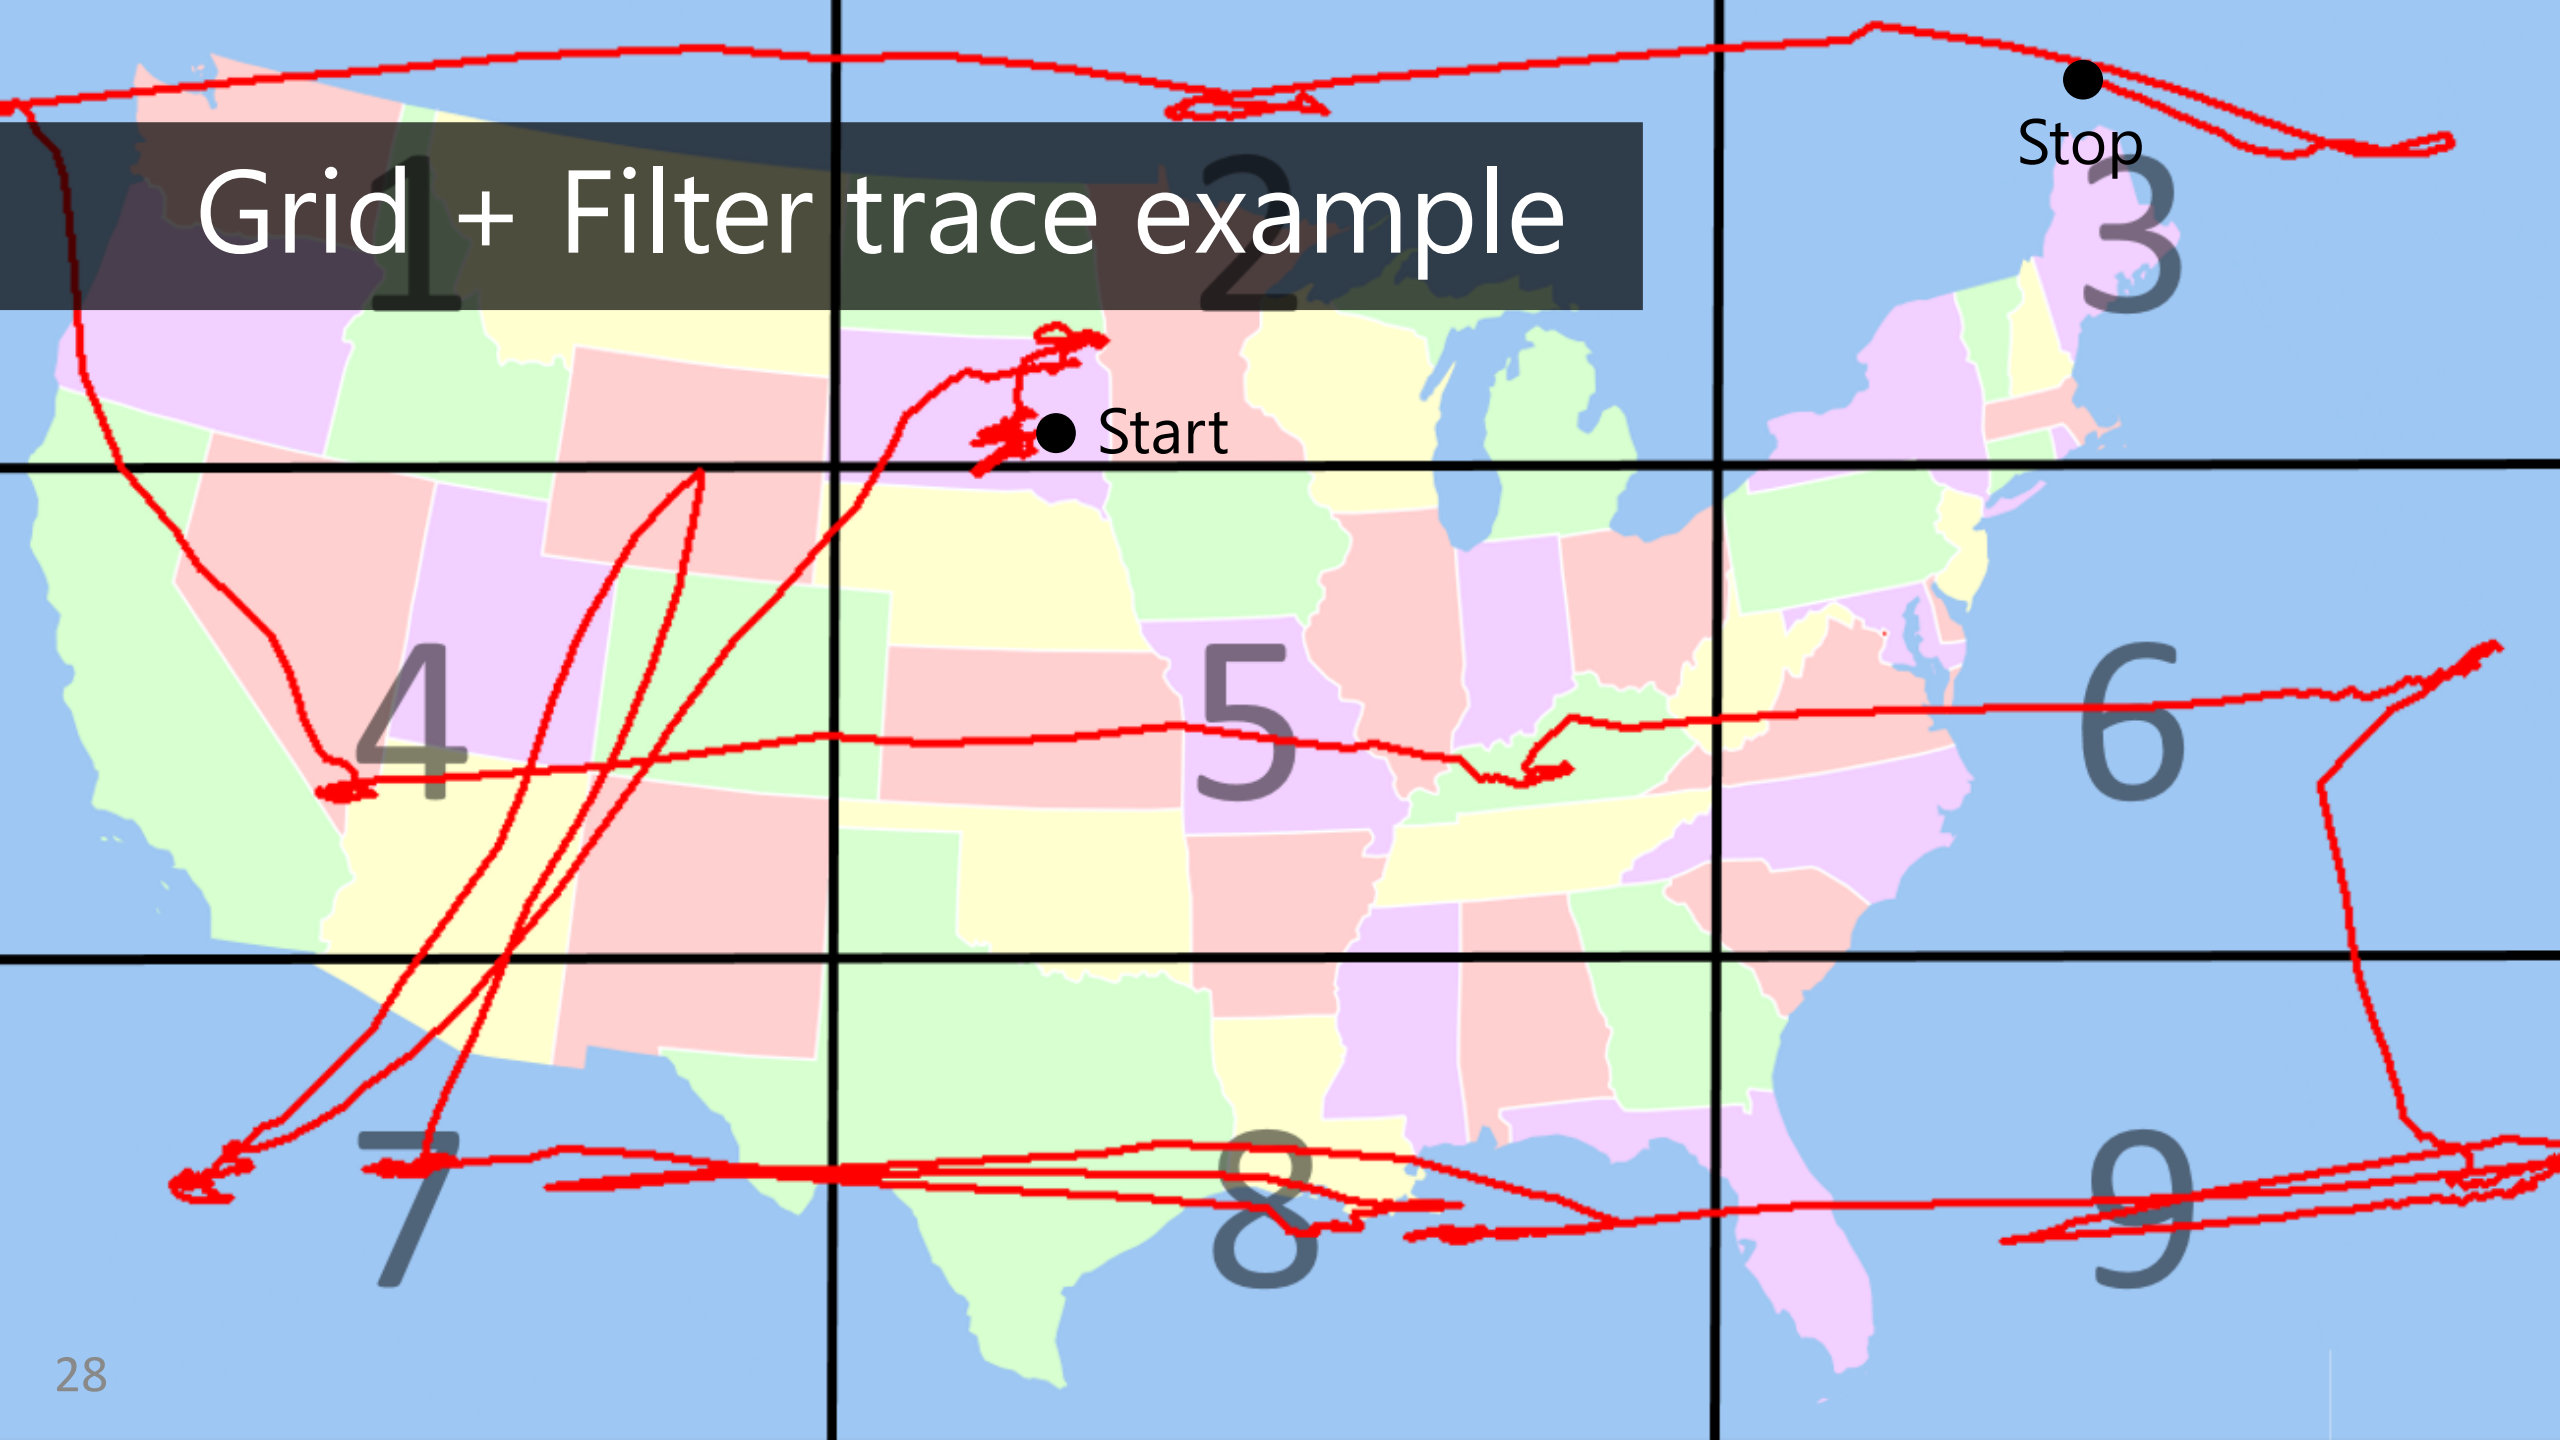

Mid-air gestures

Difficult to estimate precisely hand elevation and that they felt uncomfortable (P2, P4)

Filter trace example

Grid + Filter trace example

Conclusion

3 techniques to explore virtual spatial maps

Combined hand tracking and a smartwatch for feedback

Grid-Filter is the fastest technique but generates discomfort

Virtual techniques are usable to perform complex tasks

Future work

Two hands for virtual exploration

Future work

Smartwatches for pervasive access to maps

Leverage map exploration for visually impaired users everywhere
(office, school, home, etc.)

Use head-mounted camera

[Colaço et al., 2013]
